Characteristics and Types of CERALOCK®

MHz Band Chip CERALOCK® (CSACN/CSACM/ CSACW/CSTCC/ CSTCR/CSTCE/CSTCW Series)

The MHz band Chip CERALOCK[®] has a wide frequency range and small footprint to meet further downsizing and high-density mounting requirements.

The table shows the dimensions and two-terminals standard land patterns of the CERALOCK® CSACN/ CSACM/CSACW series.

The second table shows the dimensions and threeterminals standard land patterns of CSTCC/CSTCR/ CSTCE/CSTCW series chip resonator (built-in load capacitance type.) The carrier tape dimensions of CSTCR series are shown on the next page.

In case of CSACN and CSACM series,

the hyphen "-" is replaced to a figure which means frequency rank. This fiqure zero "0" signifies standard part number.

Principles of CERALOCK® $\overline{2}$

1. Equivalent Circuit Constants

Fig. 2-1 shows the symbol for a ceramic resonator. The impedance and phase characteristics measured between the terminals are shown in Fig. 2-2. This illustrates that the resonator becomes inductive in the frequency zone between the frequency Fr (resonant frequency), which provides the minimum impedance, and the frequency Fa (anti-resonant frequency), which provides the maximum *impedance*

It becomes capacitive in other frequency zones. This means that the mechanical vibration of a two-terminal resonator can be replaced equivalently with a combination of series and parallel resonant circuits consisting of an inductor : L, a capacitor : C, and a resistor: R. In the vicinity of the specific frequency (Refer to Note 1 on page 8), the equivalent circuit can be expressed as shown in Fig. 2-3.

Fr and Fa frequencies are determined by the piezoelectric ceramic material and the physical parameters. The equivalent circuit constants can be determined from the following formulas. (Refer to Note 2 on page 8)

Considering the limited frequency range of $Fr \leq F \leq Fa$, the impedance is given as $Z=Re+i\omega Le$ (Le ≥ 0) as shown in Fig. 2-4, and CERALOCK® should work as an inductance Le (H) having the loss Re (Ω) .

Fig. 2-1 Symbol for the Two-Terminal CERALOCK®

Fig. 2-3 Electrical Equivalent Circuit of CERALOCK®

Fig. 2-4 Equivalent Circuit of CERALOCK® in the Frequency Band Fr≦F≦Fa

Principles of CERALOCK® $2₁$

The table on this page shows a comparison of the equivalent constants between CERALOCK® and Crystal Units.

In comparison, there is a large difference in capacitance and Qm, which results in the difference of oscillating conditions, when actually operated.

The table in the appendix shows the standard values of an equivalent circuit constant for each type of CERALOCK®. Furthermore, other higher harmonic modes exist, other than the desired oscillation mode. These other oscillation modes exist because the ceramic resonator uses mechanical resonance.

Fig. 2-5 shows those characteristics.

Fig. 2-5 Spurious Characteristics of CERALOCK®

Principles of CERALOCK® $\bf{2}$

- Notes $(Note 1)$

The relationship between the size of the resonator and the resonant frequency is described as follows. For example, the frequency doubles if the thickness doubles, when thickness vibration is used. The following relationship is obtained when the length of the resonators is ℓ , the resonance frequency is Fr, the speed of sound waves travelling through piezoelectric ceramics, and the wavelength is λ .

Fr \cdot ℓ = Const. (frequency constant, Fr \cdot t for the thickness) $\lambda = 2 \ell$ $C = Fr \lambda = 2 Fr \cdot \ell$

As seen in the above formula, the frequency constant determines the size of the resonator.

(Note 2)

In Fig. 2-3, when resistance R_1 is omitted for simplification, the impedance $Z(\omega)$ between two terminals is expressed by the following formula.

$$
Z(\omega) = \frac{\frac{1}{j\omega C_0} (j\omega L_1 + \frac{1}{j\omega C_1})}{\frac{1}{j\omega C_0} + (j\omega L_1 + \frac{1}{j\omega C_1})}
$$

$$
= \frac{j(\omega L_1 - \frac{1}{\omega C_1})}{1 + \frac{C_0}{C_1} - \omega^2 C_0 L_1}
$$
When $\omega = \frac{1}{\sqrt{L_1 C_1}} = \omega r$, $Z(\omega r) = 0$

When
$$
\omega = \frac{1}{\sqrt{\text{CoCiLi}/(\text{Co}+\text{Ci})}} = \omega \text{a},\, Z\left(\omega \text{a}\right) = \infty
$$

Therefore from $\omega = 2\pi F$,

$$
Fr = \omega r / 2\pi = \frac{1}{2\pi \sqrt{L_1 C_1}}
$$

\n
$$
F_3 = \omega s / 2\pi = \frac{1}{1 - \omega} = Fr \sqrt{1 + C_1}
$$

$$
a = \omega a / 2\pi = \frac{1}{2\pi \sqrt{CoC_1 L_1 / (Co + C_1)}} = Fr \sqrt{1 + \frac{C_1}{C_0}}
$$

2. Basic Oscillation Circuits

Generally, basic oscillation circuits can be grouped into the following 3 categories.

- 1) Use of positive feedback
- 2 Use of negative resistance element
- 3 Use of delay in transfer time or phase

In the case of ceramic resonators, Crystal Units, and LC oscillators, positive feedback is the circuit of choice. Among the positive feedback oscillation circuit using an LC, the tuning type anti-coupling oscillation circuit, Colpitts and Hartley circuits are typically used. See Fig. 2-6.

In Fig. 2-6, a transistor, which is the most basic amplifier, is used.

The oscillation frequencies are approximately the same as the resonance frequency of the circuit consisting of L, $CL₁$ and $CL₂$ in the Colpitts circuit or consisting of $L₁$, $L₂$ and C in the Hartley circuit. These frequencies can be represented by the following formulas. (Refer to Note 3) on page 11.)

(Colpitts Circuit) fosc. $\dot{=}$ - $\frac{1}{2\pi\sqrt{L\cdot\frac{C_{L1}+C_{L2}}{C_{L1}+C_{L2}}}}$ $(2-4)$

(Hartley Circuit)

$$
\text{fosc.} \doteq \frac{1}{2\pi\sqrt{C(L_1+L_2)}}\tag{2-5}
$$

In an LC network, the inductor is replaced by a ceramic resonator, taking advantage of the fact that the resonator becomes inductive between resonant and antiresonant frequencies.

This is most commonly used in the Colpitts circuit. The operating principle of these oscillation circuits can be seen in Fig. 2-7. Oscillation occurs when the following conditions are satisfied.

Loop Gain
$$
G = \alpha \cdot \beta \ge 1
$$

Phase Amount
 $\theta = \theta + \theta = 360^{\circ} \times n \quad (n = 1, 2, \cdots)$ (2-6)

In Colpitts circuit, an inverter of θ 1 = 180° is used, and it is inverted more than θ 2 = 180° with L and C in the feedback circuit. The operation with a ceramic resonator can be considered the same.

Fig. 2-6 Basic Configuration of LC Oscillation Circuit

Fig. 2-7 Principle of Oscillation

$\overline{2}$ Principles of CERALOCK®

It is common and simple to utilize an inverter for the Colpitts circuit with CERALOCK®.

Fig. 2-8 shows the basic oscillation circuit with inverter. In an open loop circuit by cutting at point \circledA , it is possible to measure loop gain G and phase shift θ . Fig. 2-9 shows the actual measuring circuit, and an example of the measuring result is shown in Fig. 2-10.

 $\overline{2}$

Fig. 2-8 Basic Oscillation Circuit with Inverters

Fig. 2-9 Measuring Circuit Network of Loop Gain and Phase Shift

Fig. 2-10 Measured Results of Loop Gain and Phase Shift

Notes

(Note 3)

Fig. III shows the equivalent circuit of an emitter grounding type transistor circuit. In the figure, Ri stands for input impedance. Ro stands for output impedance and ß stands for current amplification rate.

When the oscillation circuit in Fig.2-6 is expressed by using the equivalent circuit in Fig. III, it becomes like Fig. IV. Z₁, Z₂ and Z are as shown in the table for each Hartley type and Colpitts type circuit. The following 3 formulas are obtained based on Fig.N.

Fig. IV Hartley/Colpitts Type LC Oscillation Circuits

As $i_1 \neq 0$, $i_2 \neq 0$, $i_3 \neq 0$ are required for continuous oscillation, the following conditional formula can be performed by solving the formulas of (1) , (2) and (3) on the current.

$$
\begin{cases} \beta \text{RoZ}_{1} \text{Z}_{2} = (Z_{1} + \text{R}i) Z_{2}^{2} - \{Z_{1}(Z_{2} + Z) + \\ (Z_{2} + Z + Z_{1}) \text{R}i \} (Z_{2} + \text{Ro}) \end{cases}
$$
 (4)

Then, as Z₁, Z₂ and Z are all imaginary numbers, the following conditional formula is obtained by dividing the formula (4) into the real number part and the imaginary number part.

Formula (5) represents the phase condition and formula (6) represents the power condition. Oscillation frequency can be obtained by applying the elements shown in the aforementioned table to Z₁,Z₂ and Z solving it for angular frequency ω . (Hartley Type)

$$
\omega^{2} \text{osc} = (2\pi \text{ fosc.})^{2} = \frac{1}{(\text{Li L2}) \text{ C}\{1 + \frac{\text{Li} \cdot \text{L2}}{(\text{Li} + \text{L2}) \text{ C}\text{R}i\text{R}_{0}}\}}
$$

(Colpitts Type)

$$
\omega^{2} \text{osc} = (2\pi \text{ fosc.})^{2} = \frac{1}{L \frac{CL_{1} \cdot CL_{2}}{CL_{1} + CL_{2}}} \cdot \{1 + \frac{L}{(CL_{1} + CL_{2}) \cdot R \cdot R_{0}}\}
$$

 $\ldots \ldots \ldots \ldots$ (8)

 $\cdots \cdots \cdots \cdots (7)$

In either circuit, the term in brackets will be 1 as long as Ri and $R0$ is large enough. Therefore oscillation frequency can be obtained by the following formula.

(Hartley Type) fosc.
$$
\frac{1}{2\pi\sqrt{(L_1+L_2) C}}
$$
 (9)
\n(Colpitts Type) fosc. $\frac{1}{2\pi\sqrt{L} \cdot \frac{CL_1 \cdot CL_2}{CL_1+CL_2}}$... (10)

Specifications of CERALOCK® $3\overline{)}$

1. Electrical Specifications

The frequency stability of CERALOCK® is between that of Crystal Units and LC or RC oscillators. Temperature stability is ± 0.3 to ± 0.5 % against initial values within -20 to $+80$ °C. The initial frequency precision is $\pm 0.5\%$ for standard products. The frequency of the standard CERALOCK® is adjusted by the standard measuring circuit, but the oscillation frequency may shift when used in the actual IC circuit. Usually, if the frequency precision needed for clock signal of a 1 chip microcomputer is approximately ± 2 to 3% under working conditions, CERALOCK® standard type can be used in most cases. If exact oscillation frequency is required for a special purpose, Murata can manufacture the ceramic resonator for the desired frequency. The following are the general electrical specifications of CERALOC K^{\otimes} . (As for the standard measuring circuit of oscillation frequency, please refer to the next chapter "Application to Typical Oscillation Circuits".)

Electrical Specifications of MHz Band Lead CERALOCK[®] (CSTLS Series)

Electrical specifications of CSTLS series are shown in the tables. Please note that oscillation frequency measuring circuit constants of the CSTLS \Box G56 series (with H-CMOS IC) depends on frequency.

MHz band three-terminal CERALOCK® (CSTLS Series) is built-in load capacitance.

Fig. 3-1 shows the electrical equivalent circuit.

The table shows the general specifications of the CSTLS series. Input and output terminals of the three-terminal CERALOCK® are shown in the table titled Dimensions of CERALOCK[®] CSTLS series in Chapter 1 on page 6. But connecting reverse, the oscillating characteristics are not affected except that the frequency has a slight $lag.$

Applications of Typical Oscillation Circuits 4

As described in Chapter 2, the most common oscillation circuit with CERALOCK® is to replace L of a Colpitts circuit with CERALOCK®. The design of the circuit varies with the application and the IC being used, etc. Although the basic configuration of the circuit is the same as that of Crystal Units, the difference in mechanical Q results in the difference of the circuit constant.

This chapter briefly describes the characteristics of the oscillation circuit and gives some typical examples.

1. Cautions for Designing Oscillation Circuits

It is becoming more common to configure the oscillation circuit with a digital IC, and the simplest way is to use an inverter gate.

Fig. 4-1 shows the configuration of a basic oscillation circuit with a C-MOS inverter.

INV. 1 works as an inverter amplifier of the oscillation circuit. INV. 2 acts to shape the waveform and also acts as a buffer for the connection of a frequency counter. The feedback resistance Rf provides negative feedback around the inverter in order to put it in the linear region, so the oscillation will start, when power is applied.

If the value of Rf is too large, and if the insulation resistance of the input inverter is accidentally decreased, oscillation will stop due to the loss of loop gain. Also, if Rf is too great, noise from other circuits can be introduced into the oscillation circuit. Obviously, if Rf is too small, loop gain will be low. An Rf of $1\text{M}\Omega$ is generally used with a ceramic resonator.

Damping resistor Rd provides loose coupling between the inverter and the feedback circuit and decreases the loading on the inverter, thus saving energy.

In addition, the damping resistor stabilizes the phase of the feedback circuit and provides a means of reducing the gain in the high frequency area, thus preventing the possibility of spurious oscillation.

Load capacitance CL1 and CL2 provide the phase lag of 180°

The proper selected value depends on the application, the IC used, and the frequency.

Fig. 4-1 Basic Oscillation Circuit with C-MOS Inverter

 $-(4-1)$

4 Application to Typical Oscillation Circuits

Oscillation frequency fosc. in this circuit is expressed approximately by the following equation.

$$
\text{fosc} = \text{Fr} \sqrt{1 + \frac{C_1}{C_0 + C_L}} \qquad \qquad \boxed{\qquad}
$$

Where, Fr=Resonance frequency of CERALOCK®

- C_1 : Equivalent series capacitance of
	- **CERALOCK®**
- $Co:$ Equivalent parallel capacitance of **CERALOCK®**

$$
C_{L} = \frac{C_{L1} \ C_{L2}}{C_{L1} + C_{L2}}
$$

This clearly shows that the oscillation frequency is influenced by the loading capacitance. Further caution should be paid in defining its value when a tight tolerance of oscillation frequency is required.

2. Application to Various Oscillation Circuits

Application to C-MOS Inverter

For the C-MOS inverting amplifier, the one-stage 4069 C-MOS group is best suited.

The C-MOS 4049 type is not used, because the threestage buffer type has excessive gain, which causes RC oscillation and ringing.

Murata employs the TOSHIBA TC4069UBP as a C-MOS standard circuit. This circuit is shown in Fig. 4-2. The oscillation frequency of the standard CERALOCK® (C-MOS specifications) is adjusted by the circuit in Fig. 4-2.

Fig. 4-2 C-MOS Standard Circuit

$\overline{4}$ **Application to Typical Oscillation Circuits**

Application to H-CMOS Inverter

Recently, high-speed C-MOS (H-CMOS) have been used more frequently for oscillation circuits allowing high speed and energy saving control for the microprocessor. There are two types of H-CMOS inverters: the unbuffered 74HCU series and the 74HC series with buffers.

The 74HCU system is optimum for the CERALOCK® oscillation circuit.

Fig. 4-3 shows our standard H-CMOS circuit. Since H-CMOS has high gain, especially in the high frequency area, greater loading capacitor (CL) and damping resistor (Rd) should be employed to stabilize oscillation performance. As a standard circuit, we recommend Toshiba's TC74CU04, but any 74HCU04 inverter from other manufacturers may be used. The oscillation frequency for H-CMOS specifications is adjusted by the circuit in Fig. 4-3.

Fig. 4-3 H-CMOS Standard Circuit

Characteristics of CERALOCK® Oscillation Circuits

This chapter describes the general characteristics of the basic oscillation of Fig. 4-1 (page17). Contact Murata for detailed characteristics of oscillation with specific kinds of ICs and LSIs.

1. Stability of Oscillation Frequency

Fig. 5-1 shows examples of actual measurements for stability of the oscillation frequency.

The stability versus temperature change is ± 0.1 to 0.5% within a range of -20 to $+80^{\circ}$ C, although it varies slightly depending on the ceramic material.

Influence of load capacitance (CL1, CL2) on the oscillation frequency is relatively high, as seen in formula (4-1) (Page18). It varies approximately $\pm 0.05\%$ for a capacitance deviation of $\pm 10\%$. The stability versus supply voltage is normally within $\pm 0.05\%$ in the working voltage range, although it varies with the characteristics of the IC.

5

20

Characteristics of CERALOCK[®] Oscillation Circuits $\overline{5}$

2. Characteristics of the Oscillation Level

Fig. 5-2 shows examples of actual measurements of the oscillation level versus temperature, supply voltage and load capacitance (CL1, CL2). The oscillating amplitude is required to be stable over a wide temperature range, and temperature characteristics should be as flat as possible. The graph titled Supply Voltage Characteristics in Fig. 5-2 shows that the amplitude varies linearly with supply voltage, unless the IC has an internal power supply voltage regulator.

Fig. 5-2 Examples of Actual Measurement of Oscillating Amplitude (IC: TC74HCU04(TOSHIBA), CERALOCK®: CSACW33M8X51-B0)

Characteristics of CERALOCK® Oscillation Circuit

3. Characteristics of Oscillation Rise Time

Oscillation rise time means the time when oscillation develops from a transient area to a steady state condition, at the time the power of the IC is activated. With a CERALOCK®, this is defined as the time to reach 90% of the oscillation level under steady state conditions as shown in Fig. 5-3.

Rise time is primarily a function of the oscillation circuit design. Generally, smaller loading capacitance, higher frequency of ceramic resonator, and lower mechanical Q of ceramic resonator cause a faster rise time. The effect of load capacitance becomes more apparent as the capacitance of the resonator decreases.

Fig. 5-4 shows how the rise time increases as the load capacitance of the resonator increases. Also, Fig. 5-4 shows how the rise time varies with supply voltage. It is noteworthy that the rise time of CERALOCK® is one or two decades faster than a Crystal Unit. Fig. 5-5 shows comparison of rise time between the two.

Fig. 5-3 Definition of Rise Time

Fig. 5-4 Examples of Characteristics of Oscillation Rise Time (IC: TC74HCU04 (TOSHIBA), CERALOCK®: CSACW33M8X51-B0)

Fig. 5-5 Comparison of the Rise Time of CERALOCK[®] vs. a Crystal Unit

Characteristics of CERALOCK[®] Oscillation Circuits 5

4. Starting Voltage

Starting voltage refer to the minimum supply voltage at which an oscillation circuit can operate. Starting voltage is affected by all the circuit elements, but it is determined mostly by the characteristics of the IC. Fig. 5-6 shows an example of an actual measurement for the starting voltage characteristics against the loading capacitance.

Fig. 5-6 Starting Voltage Characteristics against CL (CL1=CL2) (IC: TC74HCU04 (TOSHIBA), CERALOCK[®]: CSACW33M8X51-B0)

Application Circuits to Various ICs/LSIs 6

CERALOCK®, by making good use of the above-mentioned features, is used in a wide range of applications to various kinds of ICs. The following are a few examples of actual applications.

1. Application to Microcomputers

 $CERALOCK[®]$ is optimum for a stable oscillation element for various kinds of microcomputers : 4-bit, 8-bit and 16 -bit.

With the general frequency tolerance required for the reference clock of microcomputers at ± 2 to $\pm 3\%$, standard CERALOCK[®] meets this requirement. Please consult with MURATA or LSI manufacturers about the circuit constants, because these constants vary with frequency and the LSI circuit being used.

Fig. 6-1 to 6-5 show applications to various kinds of 4-bit microcomputers, Fig. 6-6 to 6-8 show application to 8-bit microcomputers, and Fig. 6-9 to 6-10 show application to 16bit and 32bit microcomputers.

The recomended circuit condition of many ICs has been uploaded to Murata Web site. Please access to the below URL.

$6[°]$ **Application Circuits to Various ICs/LSIs**

2. Application to Remote Control ICs

Remote controll have become an increasingly more popular feature in TVs, stereos, VCRs, and air conditioners.

Fig. 6-11 shows an example of CERALOCK® in remote control transmission ICs. Oscillation frequency is normally 3.2M to 4MHz, with 3.64MHz being the most popular. This 3.64MHz is divided by a carrier signal generator, so that a carrier of approximately 38kHz is generated.

Fig. 6-11 Application to µPD65 (Renesas Electronics)

3. Application to ICs for Office Equipment

With the applications of ICs in office machines, many CERALOCK®s are used for motor drivers/controllers/ digital signal processor (D.S.P.) in CD's ICs. Fig. 6-12 shows application example. It is believed that this type of application will increase in the future.

Fig. 6-12 Application to LC78646E (SANYO) (CD Digital Signal Processor)

4. Other Kinds of Applications to Various ICs

Other than the above-mentioned uses, CERALOCK® is widely used with ICs for voice synthesis. Fig. 6-13 shows an example of voice synthesis. We can provide CERALOCK® application data for many ICs that are not mentioned in this manual. Please

consult us for details.

6

Notice

Notice (Soldering and Mounting)

Please contact us regarding ultrasonic cleaning conditions to avoid possible damage.

Notice (Storage and Operating Conditions)

Please do not apply excess mechanical stress to the component and lead terminals at soldering.

Notice (Rating)

The component may be damaged if excess mechanical stress is applied.

Notice (Handling)

- Unstable oscillation or oscillation stoppage might occur when CERALOCK[®] is used in an improper way in conjunction with ICs. We are happy to evaluate the application circuit to help you avoid this.
- Oscillation frequency of our standard CERALOCK[®] is adjusted with our standard measuring circuit. There could be slight shift in frequency if other types of IC are used. When you require exact oscillation frequency in your application, please contact us.
- · CSACN/CSACM series is a chip resonator with 2 terminals which does not have built in load capacitors. Oscillation frequency may vary according to external load capacitance value.

Its measurement circuit for standard part number is as shown in Fig.1

Please make sure if oscillation frequency is certainly within a range of frequency tolerance that brings to essential set level performance, when using other value of constant in Fig.1

Please contact us if oscillation frequency needs to be adjusted by a chip resonator itself.

There would be some ranked part number that we could propose.

Appendix Equivalent Circuit Constants of CERALOCK®
